Mutations Associated with Reduced Susceptibility to NRTIs

Robert Shafer, MD Professor of Medicine Stanford University

This talk is about mutations responsible for resistance to nucleoside RT inhibitors most commonly referred to as NRTIs.

<u>Disclosures</u>

- Gilead Sciences (2022): Advisory board and speaking honorarium.
- ViiV Healthcare (2022): Speaking honorarium.

These are my disclosures.

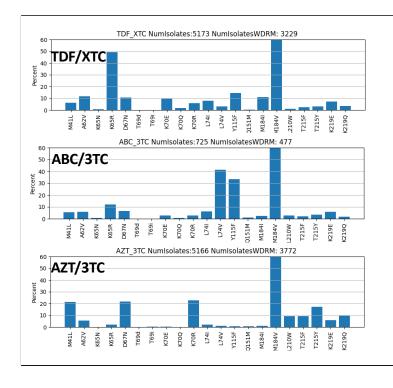

NRTIs and Resistance Mutations Adenosine analog **Guanosine analog** Thymidine analog **Cytosine analogs** Tenofovir (TFV) Zidovudine (AZT) Lamivudine (3TC) Abacavir (ABC) ⊕ ⊕ [N=N=N **Emtricitabine (FTC)** Active site Inhibitor **DRMs** Discriminatory mutations Primer unblocking mutations (TAMs) M184V/I K65R/N, K70E/Q, L74V, M41L, D67N, K70R, L210W, T215Y/F, K219Q/E Y115F

- 1. There are the five NRTIs that are currently being used.
- 2. Tenofovir has one phosphate moiety and is therefore also referred to as a nucleotide. There are two tenofovir prodrugs tenofovir disoproxil fumarate and tenofovir alafenamide.
- 3. In this presentation I use TFV as the abbreviation for tenofovir, TDF as the abbreviation for tenofovir disoproxil fumarate, and TAF as the abbreviation for tenofovir alafenamide.
- 4. <><>This figure shows part of the 3-D structure of the HIV-1 RT enzyme in which an NRTI is approaching the active site.
- 5. The most common sites of the NRTI-resistance mutations are shown in red. Most are situated close to the active site where the incoming nucleoside or nucleoside analog is added to the growing primer strand.
- 6. The NRTI-resistance mutations act by two mechanisms.
- 7. <><>The discriminatory mutations reduce the rate at which NRTIs are added to the growing viral nucleic acid primer.
- 8. <>The thymidine analog mutations or TAMs make it more likely that a chain-terminating NRTI will be removed from the growing viral nucleic acid primer. As a result, these mutations are also called primer unblocking mutations.
- 9. The TAMS are rarely, if ever, selected by current NRTI combinations. They are

primarily observed in patients with histories of ART dating back to the years in which AZT and d4T were used.

Outline

- DRMs selected by dual NRTI regimens
 - TFV/XTC
 - ABC/3TC
 - AZT/3TC
- Effects of DRMs on susceptibility
 - TFV
 - ABC
 - AZT
- Impact of DRMs on response to TFV, ABC, and 3TC
- 1. In this presentation, I will first review the DRMs selected by the three main dual NRTI combinations including TDF or TAF in combination with 3TC or FTC, ABC plus 3TC, and AZT plus 3TC.
- 2. <>Then, I'll review the effect of different DRMs and DRM combinations on susceptibility to TFV, ABC, and AZT.
- 3. <>Finally, I'll review the clinical significance of different DRMs, specifically how they influence the virological response to different NRTIs and NRTI combinations

DRMs Selected by Dual NRTIs

- M184VI in >80% of patients with DRMs.
- TDF and ABC select for the same DRMs but:
 - TDF/XTC increased A62V, K65R, K70EQTN
 - ABC/3TC increased L74V, Y115F
- AZT selects for TAMs
- MDR DRMs: T69i and Q151M exceedingly rare
- 1. These figures show the prevalence of 21 of the most common NRTI-resistance mutations in patients receiving TDF/XTC, ABC/3TC, and AZT/3TC.
- 2. Sequenced viruses were available from about 5200 persons receiving TDF/XTC of whom about 3200 had at least one NRTI DRM, from 725 persons receiving ABC/3TC of whom about 500 had at least one DRM and from about 5200 persons receiving AZT/3TC of whom about 3800 had a DRM.
- 3. <>For each of the three dual NRTI combinations, more than 80% of samples with a DRM had M184V or M184I. And as you can see from these figures M184V is much more common then M184I, which is believed to result from the increased replicative fitness of M184V relative to M184I.
- 4. <>TDFV/XTC and ABC/3TC select for overlapping profiles but TDF selects more often for A62V, K65R, and mutations at position 70 while ABC/3TC selects more often for L74V and Y115F.
- 5. About 10% of persons receiving TDF or ABC also had TAMs. This may represent persons with TDR and possibly persons who received either AZT or d4T in the past that was not recorded in their treatment history.
- 6. <>AZT selects almost exclusively for TAMs at positions 41, 67, 70, 210, 215, and 219
- 7. <>The MDR DRMs a double amino acid insertion at position 69 and Q151M

were exceedingly rare. Most of these DRMs data back to the time before 3TC and FTC became a standard part of dual NRTI therapy.

NRTI Phenotypic Susceptibility Data

3TC/FTC

- Highest levels: >200-fold
- About 5-fold reductions occur with K65R and with multiple TAMs

TFV and ABC

- Highest levels: rarely >10 fold
- TDF: low-level clinical resistance begins at about 1.5fold
- ABC: low-level clinical resistance begins at about 3fold

AZT

- Highest levels: >100-fold
- AZT: low-level clinical resistance likely begins at low levels
- 1. The range in possible reductions in susceptibility for the NRTIs. and the clinical significance of these reductions differs between NRTIs.
- 2. >200-fold reductions in 3TC/FTC susceptibility occur with M184V/I.
- 3. Much lower-level reductions in 3TC/FTC susceptibility occur with K65R and in viruses containing multiple TAMs.
- 4. We don't know the clinical significance of these smaller reductions in susceptibility.
- 5. <>For TFV and ABC, reductions in susceptibility rarely exceed 10-fold but low-level reductions in susceptibility are clinically significant.
- 6. <>Like 3TC/FTC, AZT has a high range in possible fold reductions in susceptibility.
- 7. Because AZT is weaker than other NRTIs, low-levels of reduced susceptibility as observed with certain individual TAMs are clinically significant.

6.975

https://hivdb.stanford.edu/pages/phenoSummary/Pheno.NRTI.Simple.html

>200_(n=153)

- 1. This table summarizes the effects of the most common DRMs on NRTI susceptibility. It is based on PhenoSense assay data in the Stanford HIVDR database.
- 2. As noted on the previous slide M184VI are associated with >200-fold reductions in 3TC and FTC susceptibility.
- 3. <>These mutations reduce ABC susceptibility by about 3-fold.

1181

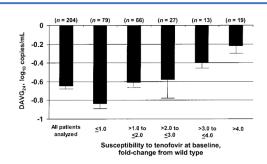

4. <>And increase AZT and TFV susceptibility by about 2-fold..

41L+210W+215Y+184V

- 5. K65R alone reduces TFV susceptibility nearly two-fold, but in combination with M184V, the median reduction in susceptibility is just 1.3-fold
- 6. K70E, a TFV selected mutation, is associated with a minimal effect on susceptibility to any of the NRTIs
- 7. <>L74V, and Y115F reduce ABC susceptibility, particularly when they occur in combination with M184V.
- 8. <>The TAMs particularly those at positions 41, 210, and 215 reduce susceptibility to each of the NRTIs. Their effect on TFV and ABC are clinically significant.

Tenofovir Intensification Study

Table 1. HIV-1 RNA response to tenofovir disoproxil fumarate (tenofovir DF), by genotype at baseline.  The 6 patients with K65R did not respond to TDF intensification.

Miller MD Genotypic and phenotypic predictors of the magnitude of response to TDF treatment in ARV-experienced patients. AIDS 2004

- 1. Much of what we know about the clinical significance of NRTI DRMs on TDF activity comes from a 2004 publication.
- This table from the paper summarizes the results from 2 placebo-controlled intensification trials in which TDF was added as a single agent to the regimen of treatment-experienced persons who had experienced VF on one or more previous NRTI-containing regimens.
- 3. The table shows that by week 24, the mean reduction in RNA level was 0.59 logs.
- 4. It was particularly high in patients with M184V and no TAMs 0.96 logs
- 5. It was low among those with 3 or more TAMs, particularly those containing M41L or L210W. These two mutations usually occur with T215Y and in fact T215Y and F were also associated with a minimal virological response to therapy.
- 6. <>The figure on the right shows that at a reduction in susceptibility above 3-4 fold, there was also a minimal response to TDF intensification.
- 7. Although the results were obtained using the Antivirogram assay which is no longer available, it does demonstrate that low level reductions in susceptibility to TDF can be clinically significant.
- 8. <>There were 6 persons with K65R and they had no virological response to TDF intensification.

Abacavir Intensification: Genotypic and Phenotypic Predictors

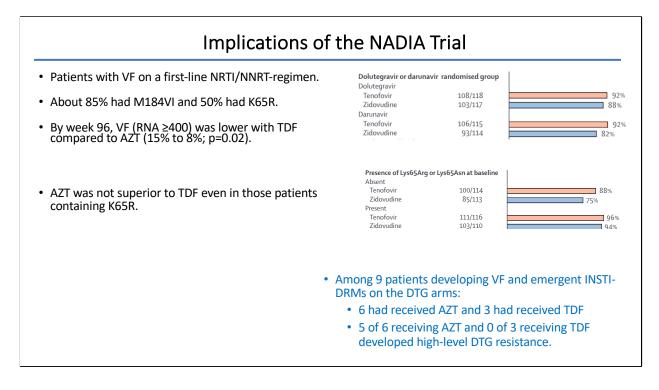

Baseline reverse transcriptase mutations	Median b	aseline	vRNA reduction (log ₁₀)
	*1114/1		(10910)
No mutations			
WT (n=15)	4.65	\longrightarrow	-0.96
1 mutation			
184V only (n=75)	3.60		-0.74
1 TAM (n=6)	3.63		-0.56
Other (n=1)	3.21		-0.60
Total (n=82)	3.60	\longrightarrow	-0.72
2 mutations			
184V + 1 TAM (n=14)	4.08		-0.95
2 TAMs (n=5)	4.51		-0.38

Total (n=28)	4.31		-0.07

- 68% had a virological response defined as ≥0.5 logs 4 weeks after ABC was added.
- No significant difference in response between those with WT virus and those with 1-2 DRMs.

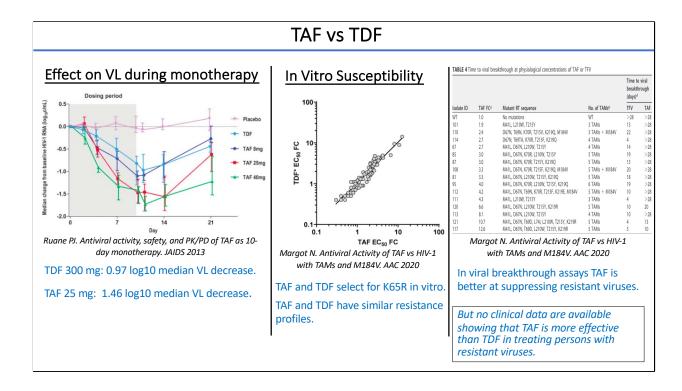

Lanier ER. Antiviral efficacy of ABC in ART-experienced adults harboring specific patterns of NRTI-resistance mutations. Antivir Ther 2004

- 1. Much of what we know about the clinical significance of NRTI DRMs on ABC activity also comes from a 2004 publication.
- 2. The table summarizes the results of a combined analysis of 5 multicenter trials in which ABC was added as a single agent to background ART in treated patients with ongoing virus replication
- 3. <>In the small group of patients with WT virus there was an approximately 1 log VL reduction measured at W4
- 4. Among 75 patients with M184V, there was an approximately three-fourths of a log reduction while among 14 patients with M184V + 1 TAM there was also a log reduction.
- 5. There was a significantly reduced response only occurred in those with 3 or more DRMs.
- 6. <>The figure on the right shows how the cut-offs on the PhenoSense phenotypic assay were developed because a reduction in response was not observed until a reduction in susceptibility of more than 4-fold occurred and no activity was observed for those with a >6-fold reduction in susceptibility. It should be noted however, that these data are based on virological response at W4 while the TDF data from the previous slide were based on virological response at W24.

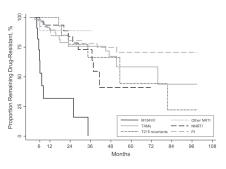

- 1. The NADIA trial is a more recent study that influenced our thinking about the clinical significance of NRTI DRMs, specifically the effect of K65R on a TDF-containing regimen.
- 2. In this trial, the participants had previously experienced VF on an NRTI/NNRTI regimen. In a factorial design, they were randomized to either DTG or DRV and to either TDF or AZT.
- 3. At baseline, 85% had an M184VI mutation and 50% had K65R.
- 4. <>By W96, trail participants were significantly more likely to have VF if they received AZT compared with TDF 15% vs 8%.
- 5. <> The superiority of TDF was greater among those receiving DRV 10% and DTG 4%.
- 5. <> Moreover, AZT was not superior to TDF in those with a baseline K65R mutation which reduces TDF susceptibility by about 2-fold but increases AZT susceptibility by about 2-fold.
- 6. <>Finally, those receiving AZT were at greater risk of developing DTG-resistance mutations. Among the 9 patients with VF and emergent INSTI DRMs on the DTG arms, 6 had received AZT and 3 had received TDF. Moreover 5 of 6 receiving AZT and 0 of 3 receiving TDF developed high-level DTG resistance.

- 1. How does TAF compare with TDF?
- 2. <>Phase 1 and 2 studies have shown that a 25-mg dose of TAF achieves higher intracellular TFV-DP concentrations than 300 mg TDF due to the greater plasma stability of TAF and intracellular conversion of TAF to TFV.
- 2. <>Monotherapy with 25 mg of TAF achieved a median 1.46-log10-unit decrease in plasma HIV-1 RNA at day 10 compared to 0.97 log10 unit decrease for 300 mg of TDF.
- 3. <>However, both TAF and TDF select for K65R in vitro and exhibit similar fold reductions in susceptibility to drug-resistant viruses in both the single cycle PhenoSense assay and the Gilead Sciences multi-cycle assays.
- 4. <>The only differences between TAF and TFV were observed in breakthrough assays with resistant viruses. Breakthrough occurred more slowly with TAF than with TFV. TFV was used in these assays because it is more stable than TDF in vitro.
- 5.<> But no clinical data are available showing that TAF is more effective than TDF in treating persons with resistant viruses.

Replication Fitness of NRTI-Associated DRMs

Jain V. Differential Persistence of Transmitted HIV-1 Drug Resistance Mutation Classes. JID 2011

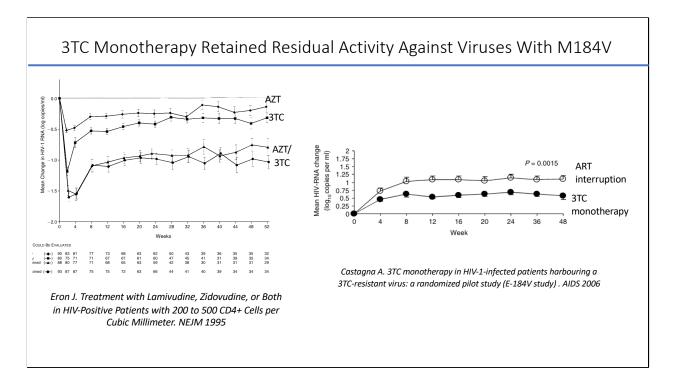

DRM	Median Rate of Loss
	In Years (95% CI)
Any NRTI	4.6 (3.3–6.4)
M184V	1.0 (0.5–2.0)
T215F	1.2 (0.3–4.6)
T215Y	1.7 (0.8–3.4)
D67N	6.0 (2.1–16.9)
M41L	8.6 (4.6–16.0)
T215	8.6 (4.6–16.0)
revertants	

Castro H. Persistence of HIV-1 Transmitted Drug
Resistance Mutations. JID 2013

DRM	Total	Clustering
41L	500	31%
67N	189	20%
219Q	151	18%
215C	128	31%

184V	169	4%
65R	13	0%

Wertheim JO. Transmission fitness of drugresistant HIV in a surveillance system transmission network. Virus Evol 2017

- 1. A discussion of NRTIs would not be complete without discussing the effect of DRMs on virological fitness and the clinical significance of the most common NRTI-resistance DRMs M184VI.
- 2. <>There have been two main papers that have looked at what happens to mutations in persons infected with a virus containing a DRM and do not go onto ARV therapy.
- 3. The figure on the left shows that M184VI mutations are no longer detectable in plasma in about 50% of patients some time between 6 and 12 months. This rate of decline is much quicker than the rate of decline of mutations associated with other drug classes and TAMS.
- 4. The table on the right is from a different study but shows very similar rates at which transmitted DRMs are outcompeted by wildtype revertants. M184VI is no longer detected by 1 year in 50% of the patients. Among the TAMs, the two with the greatest effects on susceptibility have a similar short half life, while several other TAMs usually persist for years.
- 5. <>Finally, a third study from the US CDC that created a transmission network from newly diagnosed patients found that viruses with the most impactful DRMs T215FY, M184V, and K65R were rarely found to cluster with one another suggesting that if they had been transmitted, they faded rapidly over time.

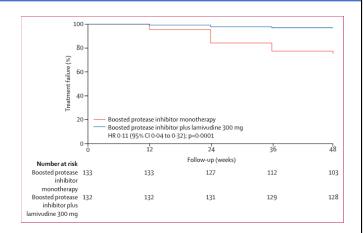

- 1. There have been more studies about the clinical significance of M184VI than any other HIV DRM.
- 2. On this and the next slide, I will present three studies indicating that viruses with M184V retain some degree of susceptibility to 3TC and FTC.
- 3. <>The figure on the left is from a clinical trial published in 1995 that shows the mean changes in HIV-1 RNA levels from patients receiving AZT monotherapy, 3TC monotherapy, and AZT/3TC combination therapy,
- 4. In this study 3TC led to a greater one log reduction in RNA levels by week 2, although virus levels rapidly rebounded coincident with development of M184VI.
- 5. Nonetheless virus levels remained about one half log lower than baseline for one year.
- Two other smaller clinical trials that I'm not showing demonstrated very similar results -- a sustained one-half log reduction in virus load associated with 3TC monotherapy treatment of viruses containing M184VI.
- 7. It is suspected that the residual activity of 3TC against viruses with M184V reflects the reduced replication capacity of viruses with this mutation.
- 8. <>The figure on the right is from the more recent E-184 open-label pilot trial that randomized patients receiving 3TC-containing ART and harboring the M184V mutation to monotherapy with 3TC 300 mg once daily or to the discontinuation of

all ARV drugs.

9. This study and at least one other similarly designed study were consistent with the very early 3TC monotherapy trials showing that the use of 3TC in persons with viruses harboring M184V was associated with a sustained approximately 0.5 log reduction in virus load.

b-PI Monotherapy vs b-PI/3TC as 2nd-Line Maintenance ART (MOBIDIP trial)

- Sub-Saharan Africa
- PLWH on 2nd-line ART regimen
 - bPI + 2 NRTIs >= 48 weeks
 - 2 VL measurements < 200 copies / 6 months
- 97% had a history of M184V/I at the time of 1st-line VF
- Randomized to bPI (DRV/r or LPV/r) vs bPI/3TC

Ciaffi L. Boosted protease inhibitor monotherapy versus boosted protease inhibitor plus lamivudine dual therapy as second-line maintenance treatment for HIV-1-infected patients in sub-Saharan Africa (ANRS12 286/MOBIDIP): a multicentre, randomised, parallel, open-label, superiority trial. Lancet HIV 2017

- 1. A third clinical trial which demonstrated the benefit of 3TC despite the presence of M184V was the MOBIDIP study.
- 2. The study population included individuals in SSA who were virologically suppressed for 6 or more months on a 2nd-line regimen containing boosted LPV or DRV.
- 3. 97% of patients had a history of M184VI following VF on a 1st-line NRTI/NNRTIregimen.
- 4. By week 48, there were 30 patients with VF in the monotherapy group but only 4 in the dual therapy group, a finding that was highly statistically significant.

Summary

- DRMs selected by dual NRTI regimens
 - TDF/XTC
 - ABC/3TC
 - AZT/3TC
- Effects of DRMs on susceptibility
 - TFV
 - ABC
 - AZT
- Impact of DRMs on response to TFV, ABC, and 3TC
- 1. In this presentation, I summarized 3 types of evidence that inform what we know about the biological and clinical significance of NRTI DRMs.
- 2. We use these data to inform the Stanford GRT interpretation program.
- 3. On the following slides, I will summarize online resources that we provide for this program.

NRTI Notes and Handout

The table lists the most common clinically significant NRTI-resistance mutations. Mutations in bold red are associated with the highest levels of reduced susceptibility or virological response to the relevant NRTI. Mutations in bold reduce NRTI susceptibility or virological response. Mutations in plain text contribute to reduced susceptibility in combination with other NRTI-resistance mutations.

There are six widely used NRTIs: the cytidine analogs 3TC and FTC (jointly referred to as XTC), the TFV prodrugs TDF and TAF, ABC, and AZT. The NRTIs are most frequently used in the following two-drug combinations: AZT/3TC, ABC/3TC, TDF/XTC, and TAF/XTC. However, XTC is frequently used alone in combination with an anchor drug that has a high genetic barrier to resistance such as DTG or DRV/r.

Assessing the antiviral activity of NRTIs and the loss of that activity through NRTI-resistance mutations is complicated for several reasons. First, the NRTIs are prodrugs that must be tri-phosphorylated (in the case of XTC, AZT, and ABC) or di-phosphorylated (in the case

	Maj	or I							bito ions		IRTI)	
		No	1-TA	Ms				T.	AMs			М	DR
	184	65	70	74	115	41	67	70	210	215	219	69	151
Cons	м	K	K	L	Y	м	D	K	L	т	K	т	Q
зтс	VI	R				Г	П	П				Ins	М
FTC	VI	R										Ins	М
ABC	VI	R	Ε	VI	F	L			W	FY		Ins	M
TFV	***	R	Ε		F	L		R	W	FY		Ins	м
AZT	**	**		*		L	N	R	w	EY	QE	Ins	M

Bold underline: High-level reduced susceptibility or virological response. **Bold:** Reduced suceptibility or virological response. **Pola:** Reduced susceptibility in combination with other NRTI-resistance mutations. Asterisk: Increased susceptibility.

M184VI: Although they cause high-level *in vitro* resistance to 3FTC, they are not contraindications to 3FTC because they increase TFV and AZT susceptibility and decrease viral replication fitness.

KESR: The most common DRM in patients with VF on a TFVregimen. It causes a clinically relevant 2-fold reduction in TFV susceptibility. However, KGSR+M184VI reduces TFV susceptibility <1.5-fold. INSTI-PI-naive patients with KGSR+M184VI who receive TFV/SFTC and a highly potent 3rd drug (e.g., DTG or DRV/r) respond as well or better than those receiving AZT/3TC even though KGSR increases AZT susceptibility.

TFV, TDF, & TAF: Tenofovir (TFV) disoproxil fumarate (TDF) and TFV alafenamide (TAF) are TFV triphosphate prodrugs, Although TDF and TAF have similar resistance profiles, Taf attains higher intracellular levels. Additional TFV-selected mutations of uncertain phenotypic and clinical significance include A62V, K65N, K70GQNTdel, and LTAL.

TAMS: Thymidine analog mutations. Selected by AZT and d4T; facilitate primer unblocking. Non-TAMs prevent NRTI incorporation. T215SCDEIVALN (T215 revertants) emerge from T215YF in the absence of NRTIs. MDE: Multidrug resistance mutations. T69 insertions occur with TAMS. Q151M occurs with non-TAMS and the accessory mutations A62V, V751, F77L, and F116Y.

https://cms.hivdb.org/prod/downloads/resistance-mutation-handout/resistance-mutation-handout.pdf

- The data that I reviewed in this presentation are summarized to a large extent in the Notes section of the HIV GRT interpretation program and in a very brief format in a PDF handout.
- 2. No major changes were made to the Notes and PDF handout since October 2022.

- 1. The HIVDB website also contains a list of all scores, which were last updated March 2024
- 2. There are individual mutation penalty scores for nearly all DRMs and several penalties that go into effect only when certain DRM combinations are present.
- 3. The total mutation penalty score for a drug is based on adding all of the individual and combination penalty scores.

NRTI Comments

Condition	Comment/ Mutation Type	Comment
115F	NRTI	Y115F causes intermediate resistance to ABC and low-level resistance to TDF.
116Y	NRTI	F116Y usually occurs in combination with the multi-NRTI resistance mutation Q151M. When it occurs alone, its clinical significance is unknown.
1181	Other	V118I is a polymorphic accessory NRTI-resistance mutation that often occurs in combination with multiple TAMs.
151L	NRTI	Q151M causes intermediate/high-level resistance to AZT and ABC, and low-level resistance to TDF, 3TC and FTC. In combination with two or more accessory mutations at positions 62, 75, 77, and 116, it confers high-level resistance to AZT and ABC and intermediate resistance to TDF, 3TC and FTC. Q151L is an extremely rare transitional mutation that may precede the emergence of the Q151M.
151M	NRTI	Q151M causes intermediate/high-level resistance to AZT and ABC, and low-level resistance to TDF, 3TC and FTC. In combination with two or more accessory mutations at positions 62, 75, 77, and 116, it confers high-level resistance to AZT and ABC and intermediate resistance to TDF, 3TC and FTC.
184VI	NRTI	M164V/I cause high-level in vitro resistance to 3TC and FTC and low/intermediate resistance to ABC (3-fold reduced susceptibility). M164V/I are not contraindications to continued treatment with 3TC or FTC because they increase susceptibility to AZT and TDF and are associated with clinically significant reductions in HIV-1 replication.
210W	NRTI	L210W is a TAM that usually occurs in combination with M41L and T215Y. The combination of M41, L210W and T215Y causes high-level resistance to AZT and intermediate resistance to ABC and TDF.
215SCDEIVALN	NRTI	T215Y/F are TAMs that causes intermediate/high-level resistance to AZT and potentially low-level resistance to ABC and TDF. T215S/C/DIE/IV/N/A/L do not reduce NRTI susceptibility but arise from viruses that once contained T215Y/F. The presence of one of these revertant mutations suggests that the patient may have once been infected with a virus containing T215Y/F.
215YF	NRTI	T215Y/F are TAMs that causes intermediate/high-level resistance to AZT and potentially low-level resistance to ABC and TDF.

https://hivdb.stanford.edu/dr-summary/comments/NRTI/

- 1. All DRMs that receive a mutation penalty score and some that don't are accompanied by a comment.
- 2. The complete list of comments for each drug class can be viewed on the website
- 3. The comments have last been updated March 2024

- 1. There is also a table that lists precomputed scores for all combinations of DRMs present in the database.
- 2. The table can be sorted by the # sequences so that the most common DRM patterns are shown at the top or by those DRMs associated with the highest scores for an NRTI.
- 3. It is very useful for us to check this table to make sure that updates to the mutation penalty scores lead to the results intended for actual virus isolates

Mutations Associated with Reduced Susceptibility to NRTIs
